| 6.2.2 | DDX | 3 |
| 6.2.3 | Testing | 3 |
| 6.2.4 | Rehab | 4 |

1 Stress injuries

Stress injuries encompass a wide variety of injuries from inflammation to full cortical breaks¹:

Stress injuries are a common type of “overuse injury” in athletic populations¹

Occur due to repetitive submaximal loading on a bone over time¹

2 Risk factors

- Athletes are at higher risk of stress injuries¹. Especially sports that combine running or jumping with high volume or intensity¹.
- LE injuries occur more often than UE¹

3 Upper Extremity injuries

UE Injuries are much less common than LE stress injuries¹. Regardless, when a stress injury occurs in the UE, it generally occurs in the ulna¹.

4 Trunk stress fractures

- Rib Stress fracture

5 Pelvis

Stress fx of the pelvis are difficult to diagnose since these present similar to other causes of groin and hip pain (i.e. adductor strain, osteitis pubis, or sacroiliitis)¹

The most common location is the ischiopubic ramus and sacrum¹. - The most common cause is running¹

6 Lower Extremity Stress Fx

6.1 Femoral neck

Femoral neck stress fractures alone make up ~11% of stress injuries in athletes¹

6.1.1 Subjective

Generally, patients complain of hip or groin pain which is aggravated with weight bearing and range of motion (especially internal rotation)¹

6.1.2 Types

There are 2 types of femoral neck stress fractures: tension-type (or distraction) fractures and compression-type fractures¹

Tension-type femoral neck stress fractures¹

- (AKA distraction type)¹
- Involve the superior-lateral aspect of the neck¹

! Important

Tension type stress fractures Have the highest risk for complete fracture¹
Thus, early detection is very important¹

Compression-type fractures

- Population
 - Commonly observed in younger athletes¹
 - Common in runners¹
- Involves the inferior-medial femoral neck¹
- Rehabilitation: non-surgical management can be attempted if there is no visible fracture line¹

6.2 Femoral shaft

Femoral shaft stress fractures are very common, especially in the military¹.

6.2.1 Subjective

Generally, patients complain of leg pain that is poorly localized and insidious¹

6.2.2 DDX

This pathology is often misdiagnosed as muscle injury¹.

6.2.3 Testing

- An exam is often nonfocal¹
- The “[fulcrum test](#)” can be helpful to localize symptoms and rule-in a femoral shaft stress fx¹

6.2.4 Rehab

If imaging does not indicate a cortical break, non-surgical rehab can be attempted¹
