

# Motor control (Overview)

Nathaniel Yomogida, SPT

Chloë Kerstein, SPT

## Table of contents

<b>1 Terminology</b>	<b>1</b>
<b>2 Motor recovery</b>	<b>2</b>
<b>3 Motor Compensation</b>	<b>2</b>

Motor control is defined as the underlying substrates of neural, physical, and behavioral aspects of movement<sup>1</sup>

Subtypes:

- Reactive motor control: Movements are adapted in response to ongoing feedback (e.g., muscle stretch causes an increase in muscle contraction in response to a forward weight shift)<sup>1</sup>
- Proactive (anticipatory) motor control: Movements are adapted in advance of ongoing movements via feedforward mechanisms (e.g., the postural adjustments made in preparation for catching a heavy, large ball)<sup>1</sup>.

## 1 Terminology

- Motor plan: an idea or plan for purposeful movement that is made up of component motor programs
- Motor program: an abstract representation that, when initiated, results in the production of a coordinated movement sequence<sup>1</sup>
- **Motor learning**: a set of internal processes associated with feedback or practice leading to relatively permanent changes in the capability for motor skill<sup>1</sup>
- **Motor recovery**: the reacquisition of movement skills lost through injury Schema: a set of rules, concepts, or relationships formed on the basis of experience<sup>1</sup>
- **Schema**: serve to provide a basis for movement decisions and are stored in memory for the reproduction of movement<sup>1</sup>

- [Recall schema](#): the relationship among past parameters, past initial conditions, and the movement outcomes produced by these combinations<sup>1</sup>
- [Recognition schema](#): the relationship among past initial conditions, past movement outcomes, and the sensory consequences produced by these combinations<sup>1</sup>
- Task analysis: a process of determining the underlying abilities and structure of a task or occupation<sup>1</sup>
- Task organization: how the components of a task are interrelated or interdependent<sup>1</sup>
  - Low organization: Task components are relatively independent<sup>1</sup>.
  - High organization: Task components are highly interrelated<sup>1</sup>.

## 2 Motor recovery

[Motor recovery](#) refers to the reacquisition of movement skills lost through injury<sup>1</sup>.

## 3 Motor Compensation

[Motor compensation](#) differs from motor recovery since refers to changing motor plans instead of regaining old methods. [Motor compensation](#) refers to the performance of an old movement in a new manner that can be achieved through [adaptive compensation](#) or [behavioral substitution](#)<sup>1</sup>.
